Learning Objectives

- Implement single-sample and buffered ADC data acquisitions.
- $\bullet\,$ Implement fixed-reference and differential ADC inputs.
- Implement synchronous and asynchronous ADC acquisitions.

Git Best Practices

- Use best practices for version control (branching, commit messages, etc.).
- Do all development on a dedicated branch that is merged into main once it is functional.
- Commits should be very specific to the changes/additions you are making to your code. This will help you and others understand what you did and why you did it.
- On a given development branch, try to implement one small piece of functionality at a time, commit it, and then move on to the next piece of functionality.

Important

You do not want one, monolithic git commit right before you submit your project.

Firmware Expectations

- All firmware should be written using the **State Machine Framework**.
- Choose your states for each part as a firmware engineer would, using what you have learned so far this semester.
- Timers, work queues, callbacks, and interrupts should be used as appropriate.
- All good coding practices developed this semester should be followed.
- Use logging to display state information and other relevant information, warnings, and errors. Debugging log messages can remain in the code, but the logging level should be submitted at the INF level.
- Include a state diagram in your repository (state_diagram.png) using UML (state_diagram.puml) or some equivalent.

ADC Single Sampling

Firmware Functional Specifications

- Do all development and testing for Part I on a development branch called adc_single_sample.
- LED and BUTTON number references below are based on Devicetree labels (not the annotation on the DK board itself).
- There should be a heartbeat LED (LEDO) that blinks at 1 Hz with a 25% duty cycle at all times when the firmware is running.

- When BUTTONO is pressed, make a measurement using the AINO channel of the ADC.
 - Use the ADC_REF_INTERNAL reference voltage.
 - Linearly map 0-3.0 V measured on the AINO input to an LED1 blink rate of 1-5 Hz (e.g., $0 \text{ V} \rightarrow 1 \text{ Hz}$; $3.0 \text{ V} \rightarrow 5 \text{ Hz}$) with a duty cycle of 10%.
 - LED1 should remaining blinking for 5 seconds after the button has been pressed.

Testing

For the following testing, you can use a power supply to provide known voltage input to AINO.

• Quantify how linear the relationship is between the voltage applied to AINO and the LED1 blinking frequency by acquiring data to perform a linear regression of these variables and analyzing the resultant R^2 , slope and intercept.

Remember that single data points for any single input voltage pair is not adequate; multiple measurements should be made and error bars presented on all plots.

Tip

The bme554.py library has a functions called plot_with_fit() and calculate_confidence_intervals() that can help.

- Quantify the accuracy of the LED1 10% duty cycle for each frequency that you measure.
- Quantify the accuracy of LED1 5 second ontime duration.
- Present all of these data, your analysis and your interpretation in a new Jupyter notebook named testing_testing_adc.ipynb.

Commit-n-Merge Single Sample Acquisition

- Update your state diagram.
- Merge your completed adc_single_sample branch into your main branch using a Merge Request on Gitlab.
- Create an annotated tag of your main branch with all part of this lab merged in called v2.0.0.

Buffered Differential ADC Sampling

Firmware Functional Specifications

In a new development branch called diff_adc, add the following functionality to your firmware:

- When you press BUTTON1, add an additional differential ADC measurement using AIN1 and AIN2.
- Choose the reference voltage, gain, bit depth and acquisition time to adequately sample at least 20 cycles of a 10 Hz sinusoidal signal ($V_{pp} = 2 \text{ V}$). 0 Implement the extra_sampling buffering of the ADC for this differential sinusoidal signal measurement so that all of the data are stored in an array in a single adc read() call (i.e., you are not using a kernel call for every sample).
- Disable the BUTTON1 while your device is reading AIN1 and AIN2 and performing calculations below. 0 Write a library called calc_cycles that calculates the number of sampled sinusoidal cycles in the buffered ADC samples.
 - This can be rounded to the nearest integer, depending on your algorithm.
 - Have this calculated number of cycles displayed using LOG_INF() in the console.
- Write log messages to your serial terminal that dsplay a HEX array of the buffered ADC samples.
- Update your state diagram for this new functionality.

Warning

Be careful for the log message memory consumption! You may need to adjust the stack size of the appropriate thread if you are getting memory-related firmware faults.

Remember that the data will be saved using two's complement.

Testing

- Input a 10 Hz sinusoidal signal with a 2 V V_{pp} into the differential AIN1 and AIN2 inputs.
- Create a plot of your input signal and the buffered ADC samples (using the HEX array output).

Tip

There are helper functions in bme554.py called read_hex_data() and unwrap_twos_completely().

The HEX data array from the terminal can be copied and pasted into a text file in your git repository to read into your Jupyter notebook for analysis.

- Discuss any differences between the input signal and your sampled signal.
- Calculate the frequency of your sampled signal and compare it to your input frequency.
- Add this analysis to a new section called Buffered Differential ADC Sampling in testing/testing_adc.ipynb.

Commit-n-Merge Buffered Acquisition

- Merge your completed diff_adc branch into your main branch using a Merge Request on Gitlab.
- Create an annotated tag of your main branch with all part of this lab merged in called v2.1.0.

Asynchronous ADC Sampling

Firmware Functional Specifications

In a new development branch called async_adc, add the following functionality to your firmware:

- Refactor your blocking, synchronous buffered ADC sequence acquisition to an asynchronous acquisition that populates the same array that was populated with the synchronous approach.
- Utilize the 3 Zephyr macros presented in lecture to modulate the behaviour of the asynchronous callback function.

Testing

- Repeat the testing you performed in the syncronous section in a new section called Asynchronous ADC Sampling in testing/testing_adc.ipynb.
- Discuss the benefits and drawbacks of the asyncronous ADC sequence sampling compared to the synchronous sampling.

Commit-n-Merge Asynchronous Sampling

- Merge your completed async_adc branch into your main branch using a Merge Request on Gitlab.
- Create an annotated tag of your main branch with all part of this lab merged in called v2.2.0.

Timer-Based Single Sampling to Array

Firmware Functional Specifications

In a new development branch called timer_adc, add the following functionality to your firmware:

Refactor your firmware to use a kernel timer to do single ADC samples that are sequentially stored in the array that was associated with the ADC sequence in the previous two sections.

Testing

- Repeat the testing you performed in the asyncronous section in a new section called Timer-Based Single Sampling to Array in testing/testing_adc.ipynb.
- Discuss the benefits and drawbacks of using a timer-based ADC sampling scheme compared to the previous approaches when trying to accurately sample a sinusoidal signal.

Commit-n-Merge Timer Sampling

- Merge your completed timer_adc branch into your main branch using a Merge Request on Gitlab.
- Create an annotated tag of your main branch with all part of this lab merged in called v2.3.0.

How to Ask for Help

- 1. If you have a general / non-coding question, you should ask your TAs / Dr. Palmeri on Ed to allow any of them to respond in a timely manner.
- 2. Push you code to your GitLab repository, ideally with your active development on a non-main branch.
- 3. Create an Issue in your repository.
 - Add as much detail as possible as to your problem, and add links to specific lines / section of code when possible.
 - Assign the label "Bug" or "Question", as appropriate.
 - Be sure to specify what branch you are working on.
 - Assign the Issue to one of the TAs.
 - If your TA cannot solve your Issue, they can escalate the Issue to Dr. Palmeri.
- 4. You will get a response to your Issue, and maybe a new branch of code will be pushed to help you with some example syntax that you can use git diff to visualize.
